Using the PIC18F4620 or PIC18F4520

Historically, MIOS was developed to run on a core module stuffed with a PIC18F452. Recently, the PIC18F4620 has become available. It is near code-compatible with the 452, but features a significant increase in RAM/EEPROM/Codespace. See the PIC18F4620 page for details.

The following are intructions on converting old apps, and developing new apps, to run on the PIC18F4620. Small changes to the procedure make it compatible with the PIC18F4520 also.

OS Layers

MIOS v1.9b or above is required. You will need to download the MIOS source from The uCApps.de Download Page or Directly. I recommend checking the first link for the latest version, as the '4620 is current in beta.

The Bootloader and MIOS recompile steps which follow should not be necessary for most cases of '4620 use, as these components are now available precompiled and packaged in a zip file hosted on uCApps.de Instructions follow for reference only, or for '4520 use.

Bootloader

Bootloader v1.2, which is packaged with MIOS v1.9 and up, will need to be recompiled as follows:

- Extract the MIOS source files from the zip
- Edit bootloader\main.asm
- Change

#define PIC_DERIVATIVE_TYPE 0

То

#define PIC_DERIVATIVE_TYPE 1

• Burn the hex file to the PIC **Fix Me!** wiki link

MIOS

The MIOS Operating System itself must also be compiled, as follows:

- Edit src\mios.h from the MIOS source files
- Change

#define PIC_DERIVATIVE_TYPE 0

То

#define PIC_DERIVATIVE_TYPE 1

- Compile the project **Fix Me!** wiki link
- Upload the hex file with MIOS Studio

Please note that the above instructions should work for PIC18F4520 also. The only difference is that the PIC_DERIVATIVE_TYPE should be '2', not '1'. This stands for all of the following instructions.

Application Layer

Once your PIC18F4620 has the Bootloader burned onto it, and MIOS uploaded, you are ready to upload your application. A few modifications may be required:

Migration

If you have an existing ASM-based application, which is designed for MIOS v1.8 or lower, then you will need to migrate the application to support MIOS v1.9

- Extract the 'migration' folder from MIOS source zip file
- Overwrite the files contained in the source of your application.

Take note that this may overwrite customisations you have made to your application, so please take a backup first, and a copy for comparison with the new files.

ASM

If your application is either:

- 1. a freshly migrated application (as above)
- 2. a brand new ASM-based project based on a skeleton >= v1.9
- 3. an ASM-based application which already requires MIOS v1.9 or greater (like MBSID v1.7303)

Then the following steps are required:

- Edit mios.h in the source of your application
- Change

#define PIC_DERIVATIVE_TYPE 0

То

```
#define PIC_DERIVATIVE_TYPE 1
```

• Upload the hex file with MIOS Studio

С

If your application is C-based, then the following steps are required. Some are optional recommendations, as noted.

Header and Library

In the case that you should need to take advantage of the additional EEPROM on the newer PICs, the following alterations to the library and header are necessary:

- Edit pic18f452.c in the source of your application
- Change

```
sfr at 0xfa9 EEADR;
sfr at 0xfab RCSTA;
```

То

```
sfr at 0xfa9 EEADR;
sfr at 0xfaa EEADRH;
sfr at 0xfab RCSTA;
```

- Edit pic18f452.h in the source of your application
- Change

extern __sfr __at 0xfa9 EEADR; extern __sfr __at 0xfab RCSTA;

То

| extern | sfr | at | 0xfa9 | EEADR; |
|--------|-----|----|-------|---------|
| extern | sfr | at | 0xfaa | EEADRH; |
| extern | sfr | at | 0xfab | RCSTA; |

Note that the filenames stay as pic18f452.*, regardless of the PIC model we are actually using. For our purposes, SDCC considers the '4620 to be the same as a '452.

C-Wrapper

The C-Wrapper will need to be edited as follows:

- In the source of your application, edit mios_wrapper\mios.h
- Change

```
#define PIC_DERIVATIVE_TYPE 0
```

То

#define PIC_DERIVATIVE_TYPE 1

If you want to use this function, you may want to apply a small fix to the DEC2BCD Helper:

- In the source of your application, edit mios_wrapper\mios_wrapper.asm
- Change

global _MIOS_HLP_Dec2BCD

```
movwf MIOS_PARAMETER1 //Moves W (the low byte of the 16-bit
integer) into MIOS_PARAMETER1 - That ain't right. See below from the MIOS
Function Reference
movff FSR0L, FSR2L //These guys
movf PREINC2, W //Put the high byte in W. D'oh!
goto MIOS_HLP_Dec2BCD
```

5/8

global _MIOS_HLP_Dec2BCD

movff FSR0L, FSR2L movf PREINC2, MIOS_PARAMETER1 MIOS_PARAMETER1. Yay! //The low byte is already in W

//These guys
//Put the high byte in

goto MIOS_HLP_Dec2BCD

Linker Script

Modifications should be made to the linker script in order to take advantage of the additional capabilities of the 4620/4520. If you are using a standard, PIC18F452-based application, these steps should not be necessary. These procedures are intended for applications being developed which will require the additional capabilities of the newer PICs.

Extend Codepage

Both the 4620 and 4520 have extended code memory. To utilise this fully, make the following alterations:

- In the source of your application, edit project.lkr
- Change

| CODEPAGE | NAME=page | START=0x3000 | END=0x7FFF |
|----------|-----------|--------------|------------|
| То | | | |
| CODEPAGE | NAME=page | START=0x3000 | END=0×FFFF |

Add Databanks

In order to give our application the ability to recognise all that lovely, lovely RAM in the newer '4620 and '4520 PICs, one or a mixture of the following options is required:

Standard Bank Size

- In the source of your application, edit project.lkr
- Change

| DATABANK | NAME=miosram_u | START=0x380 | END=0x5FF | PROTECTED |
|------------|----------------|-------------|-----------|-----------|
| ACCESSBANK | NAME=accesssfr | START=0×F80 | END=0×FFF | PROTECTED |

То

using_pic18f4620 http://www.midibox.org/dokuwiki/doku.php?id=using_pic18f4620&rev=1151726104

| DATABANK | NAME=miosram_u | START=0x380 | END=0x5FF | PROTECTED |
|------------|----------------|-------------|-----------|-----------|
| DATABANK | NAME=gpr6 | START=0x600 | END=0×6FF | |
| DATABANK | NAME=gpr7 | START=0x700 | END=0x7FF | |
| DATABANK | NAME=gpr8 | START=0x800 | END=0x8FF | |
| DATABANK | NAME=gpr9 | START=0x900 | END=0×9FF | |
| DATABANK | NAME=gpr10 | START=0xA00 | END=0×AFF | |
| DATABANK | NAME=gpr11 | START=0×B00 | END=0×BFF | |
| DATABANK | NAME=gpr12 | START=0xC00 | END=0×CFF | |
| DATABANK | NAME=gpr13 | START=0xD00 | END=0×DFF | |
| DATABANK | NAME=gpr14 | START=0×E00 | END=0×EFF | |
| DATABANK | NAME=gpr15 | START=0×F00 | END=0×F7F | |
| | | | | |
| ACCESSBANK | NAME=accesssfr | START=0×F80 | END=0×FFF | PROTECTED |
| | | | | |

Extended Bank Capacity

Last update: 2006/10/15 09:35

The above change will enable SDCC to allocate the variables in your application to any of the specified banks above. The very observant among you may have noticed that these banks are 256 bits each.... So what happens if you want to use a variable which is greater than 256 bits in size, such as a large array, or string of characters? For this, you will need to create a bank of extended size, and you will need to direct your application to use that bank to store your large variable.

In order to create memory banks of extended capacity, it is necessary to section off a greater range than those given above. A good way to go about this is to combine two or more of the default banks. The following are examples of this.

Making a single, 512-bit bank:

| DATABANK NAME=miosram_u // DATABANK NAME=gpr6 // Remove this bank | START=0x380 START=0x600 | END=0x5FF END=0x6FF | PROTECTED |
|---|----------------------------|------------------------|-----------|
| <pre>// DATABANK NAME=gpr7 // And remove this bank</pre> | START=0x700 | END=0x7FF | |
| DATABANK NAME=gpr67 // And create this one out | START=0x600 of the two | END=0x7FF | |
| DATABANK NAME=gpr8 | START=0x800 | END=0x8FF | |
| DATABANK NAME=gpr9 | START=0×900 | END=0x9FF | |
| DATABANK NAME=gpr10 | START=0×A00 | END=0×AFF | |
| DATABANK NAME=gpr11 | START=0×B00 | END=0xBFF | |
| DATABANK NAME=gpr12 | START=0×C00 | END=0xCFF | |
| DATABANK NAME=gpr13 | START=0×D00 | END=0xDFF | |
| DATABANK NAME=gpr14 | START=0×E00 | END=0×EFF | |
| DATABANK NAME=gpr15 | START=0×F00 | END=0×F7F | |
| ACCESSBANK NAME=accesssfr | START=0×F80 | END=0×FFF | PROTECTED |

Note that the START of the bank is the same as the START of the first bank removed, and the END of the bank, is the same as the END of the last bank removed.

This can be extended into larger ranges, and multiple customised ranges, as below:

| DATABANK NAME=miosram_u // DATABANK NAME=gpr6 // Remove this bank, | | END=0x5FF END=0x6FF | PROTECTED |
|--|---------------------|------------------------|----------------|
| <pre>// DATABANK NAME=gpr7 // And remove this bank,</pre> | START=0x700 | END=0x7FF | |
| DATABANK NAME=gpr67 | START=0×600 | END=0x7FF | |
| // And create this 512-bit | bank out of the two | 256-bit banks. | |
| DATABANK NAME=gpr8 | START=0×800 | END=0x8FF | |
| DATABANK NAME=gpr9 | START=0×900 | END=0×9FF | |
| DATABANK NAME=gpr10 | START=0×A00 | END=0×AFF | |
| // DATABANK NAME=gpr11 | START=0×B00 | END=0×BFF | |
| <pre>// Remove this bank,</pre> | | | |
| // DATABANK NAME=gpr12 | START=0×C00 | END=0×CFF | |
| <pre>// And remove this bank,</pre> | | | |
| // DATABANK NAME=gpr13 | START=0×D00 | END=0xDFF | |
| <pre>// And remove this bank,</pre> | | | |
| // DATABANK NAME=gpr14 | START=0×E00 | END=0×EFF | |
| <pre>// And remove this bank!</pre> | | | |
| | START=0×B00 | | |
| <pre>// And create this 1024-big</pre> | | it of the four 2 | 256-bit banks. |
| DATABANK NAME=gpr15 | START=0×F00 | END=0×F7F | |
| | | | |
| ACCESSBANK NAME=accesssfr | START=0×F80 | END=0×FFF | PROTECTED |

Or of course you could make the whole lot into one bank if you wanted to:

| DATABANK DATABANK // That's | NAME=miosram_u NAME=gpr615 almost 2.5kilobi | START=0×600 | END=0x5FF END=0xF7F | PROTECTED |
|-----------------------------------|---|-------------|------------------------|-----------|
| ACCESSBANK | NAME=accesssfr | START=0×F80 | END=0×FFF | PROTECTED |

Add Sections

In order to assist in the use of these memory banks, we can give create 'sections' with names, and those names can be referenced in our code later on. I will use the 2nd example above, to demonstrate:

| DATABANK NAME=gpr67 START=0x600 END=0x7FF // And create this 512-bit bank out of the two 256-bit banks. DATABANK NAME=gpr8 START=0x800 END=0x8FF DATABANK NAME=gpr9 START=0x900 END=0x9FF | |
|--|--|

MIDIbox - http://www.midibox.org/dokuwiki/

DATABANK NAME=qpr10 START=0xA00 END=0xAFF DATABANK NAME=gpr1114 START=0xB00 END=0xEFF // And create this 1024-bit (1 Kilobit) bank out of the four 256-bit banks. DATABANK NAME=qpr15 START=0xF00 END=0xF7F ACCESSBANK NAME=accesssfr START=0xF80 END=0xFFF PROTECTED SECTION NAME=CONFIG ROM=config // This SECTION entry will already exist in the file. Do NOT alter this line! SECTION NAME=gpr8 RAM=gpr8 // This creates a SECTION called 'gpr8' which references the normal 256-bit bank 'gpr8' SECTION RAM=gpr67 NAME=b512// This creates a SECTION called 'b512' which references our 512-bit bank SECTION NAME=b1024 RAM=gpr1114 // This creates a SECTION called 'b1024' which references our 1kb bank

using pic18f4620 http://www.midibox.org/dokuwiki/doku.php?id=using pic18f4620&rev=1151726104

You may create as many or as few sections as you require for your application.

Application Code

Last update: 2006/10/15 09:35

Once these sections are created, you can use them within your application, by forcing a variable to be stored within that section. This is done using the 'udata' pragma statement with the following syntax:

#pragma udata section_name variable_name

For example, referencing the above section:

```
#pragma udata b512 MIDI_Table // This means "store a variable named
'MIDI_Table' in the SECTION named 'b512'
unsigned int MIDI_Table[512]; // Declare the array named 'MIDI_Table',
and now it will be stored in 'b512'
```

Still reading? ;)
