# Using the PIC18F4620 or PIC18F4520

Historically, MIOS was developed to run on a core module stuffed with a PIC18F452. Recently, the PIC18F4620 has become available. It is near code-compatible with the 452, but features a significant increase in RAM/EEPROM/Codespace. See the PIC18F4620 page for details.

The following are intructions on converting old apps, and developing new apps, to run on the PIC18F4620. Small changes to the procedure make it compatible with the PIC18F4520 also.

# **OS Layers**

MIOS v1.9b or above is required. You will need to download the MIOS source from The uCApps.de Download Page or Directly. I recommend checking the first link for the latest version, as the '4620 is current in beta.

The Bootloader and MIOS recompile steps which follow should not be necessary for most cases of '4620 use, as these components are now available precompiled and packaged in a zip file hosted on uCApps.de Instructions follow for reference only, or for '4520 use.

# Bootloader

Bootloader v1.2, which is packaged with MIOS v1.9 and up, will need to be recompiled as follows:

- Extract the MIOS source files from the zip
- Edit bootloader\main.asm
- Change

#define PIC\_DERIVATIVE\_TYPE 0

То

#define PIC\_DERIVATIVE\_TYPE 1

• Burn the hex file to the PIC **Fix Me!** wiki link

## MIOS

The MIOS Operating System itself must also be compiled, as follows:

- Edit src\mios.h from the MIOS source files
- Change

#define PIC\_DERIVATIVE\_TYPE 0

То

#define PIC\_DERIVATIVE\_TYPE 1

- Compile the project **Fix Me!**
- also see: Compiling the MIDIbox source on Linux using GPASM (Linux, Mac) instead of MPLAB (Windows)

wiki link

• Upload the hex file with MIOS Studio

*Please note that the above instructions should work for PlC18F4520 also. The only difference is that the PlC\_DERIVATIVE\_TYPE should be '2', not '1'. This stands for all of the following instructions.* 

# **Application Layer**

Once your PIC18F4620 has the Bootloader burned onto it, and MIOS uploaded, you are ready to upload your application. A few modifications may be required:

# Migration

If you have an existing ASM-based application, which is designed for MIOS v1.8 or lower, then you will need to migrate the application to support MIOS v1.9

- Extract the 'migration' folder from MIOS source zip file
- Overwrite the files contained in the source of your application.

Take note that this may overwrite customisations you have made to your application, so please take a backup first, and a copy for comparison with the new files.

## ASM

If your application is either:

- 1. a freshly migrated application (as above)
- 2. a brand new ASM-based project based on a skeleton >= v1.9
- 3. an ASM-based application which already requires MIOS v1.9 or greater (like MBSID v1.7303)

Then the following steps are required:

- Edit mios.h in the source of your application
- Change

#define PIC\_DERIVATIVE\_TYPE 0

То

```
#define PIC_DERIVATIVE_TYPE 1
```

• Upload the hex file with MIOS Studio

# С

If your application is C-based, then the following steps are required. Some are optional recommendations, as noted.

#### Note on compile errors

When compiling your C-based application, you may see an error such as this:

```
Linking project
warning: processor mismatch in "_output\mios_wrapper.o"
```

This error is caused by SDCC compiling the application for the PIC18F452. Fortunately, the code is compatible between the two chips, so this error can be ignored. Thanks to bill, for having the guts to put the app on his PIC, and confirm that this was the case ;)

## **Header and Library**

In the case that you should need to take advantage of the additional EEPROM on the newer PICs, the following alterations to the library and header are necessary:

- Edit pic18f452.c in the source of your application
- Change

sfr at 0xfa9 EEADR; sfr at 0xfab RCSTA;

То

sfr at 0xfa9 EEADR; sfr at 0xfaa EEADRH; sfr at 0xfab RCSTA;

• Edit pic18f452.h in the source of your application

• Change

extern \_\_sfr \_\_at 0xfa9 EEADR; extern \_\_sfr \_\_at 0xfab RCSTA;

То

extern	sfr	at	0xfa9	EEADR;
extern	sfr	at	0xfaa	EEADRH;
extern	sfr	at	0xfab	RCSTA;

Note that the filenames stay as pic18f452.\*, regardless of the PIC model we are actually using. For our purposes, SDCC considers the '4620 to be the same as a '452.

## **C-Wrapper**

The C-Wrapper will need to be edited as follows:

- In the source of your application, edit mios\_wrapper\mios.h
- Change

#define PIC\_DERIVATIVE\_TYPE 0

То

#define PIC\_DERIVATIVE\_TYPE 1

If you want to use this function, you may want to apply a small fix to the DEC2BCD Helper:

//Put the high byte in W. D'oh!

PREINC2, W

MIOS\_HLP\_Dec2BCD

<ul> <li>In the source of your application, edit mios_wrapper\mios_wrapper.asm</li> <li>Change</li> </ul>						
global _MIOS_HLP_Dec2BCD						
<pre>movwf MIOS_PARAMETER1 integer) into MIOS_PARAMETER1 - That a Function Reference</pre>	//Moves W (the low byte of the 16-bit ain't right. See below from the MIOS					
movff FSR0L, FSR2L	//These guys					

То

movf

goto

global _MIOS_HLP_Dec2BCD	<pre>//The low byte is already in W</pre>
<pre>movff FSR0L, FSR2L movff PREINC2, MIOS_PARAMETER1 MIOS_PARAMETER1. Yay!</pre>	//These guys //Put the high byte in
goto MIOS_HLP_Dec2BCD	

## **Linker Script**

Modifications should be made to the linker script in order to take advantage of the additional capabilities of the 4620/4520. If you are using a standard, PIC18F452-based application, these steps should not be necessary. These procedures are intended for applications being developed which will require the additional capabilities of the newer PICs.

### **Extend Codepage**

Both the 4620 and 4520 have extended code memory. To utilise this fully, make the following alterations:

- In the source of your application, edit project.lkr
- Change

CODEPAGE	NAME=page	START=0x3000	END=0x7FFF
То			
CODEPAGE	NAME=page	START=0x3000	END=0xFFFF

If you are using a GLCD with your PIC18F4620 the GLCD Font of the MIOS will be overwritten by this change though, as it lies in the range of 0x7C00-0x7FFF. There are <u>two</u> approaches to prevent this (also see forum thread http://www.midibox.org/forum/index.php?topic=7540.0):

• To leave out the Font space in the PIC's code memory, change

	CODEPAGE	NAME=page	START=0x3000	END=0x7FFF	
--	----------	-----------	--------------	------------	--

То

CODEPAGE	NAME=page0	START=0×3000	END=0x7BFF
CODEPAGE	NAME=page1	START=0×8000	END=0xFFFF

or try this solution from TK:

- copy the mios\_glcd\_font.inc file from the MIOS release into your application directory, rename it to mios\_glcd\_font.asm
- add following code to the file header:

```
LIST P=PIC18F4620, R=DEC
DEFAULT_FONT code
FONT_ENTRY MACRO width, height, x0, char_offset
dw ((height) << 8) | (width), ((char_offset) << 8) | (x0)
ENDM
```

- change the "org" (start address) from 0x7cfc to 0xfcfc
- add a "END" at the file footer
- add the new .asm file to the MAKEFILE.SPEC (behind the MK\_SET\_OBJ statement)
- change the font pointer within the Init() routine:

```
void Init(void)
{
MIOS_GLCD_FontInit(0xfcfc);
}
```

 if you are working under MacOS or Linux, type "perl tools/mkmk.pl MAKEFILE.SPEC; make", under DOS just type "make"

The first approach has the advantage, that it isn't required to upload the font again and again with each program update. The second approach that new fonts can be inserted into the project in a similar way. Please see the forum article mentioned above on instructions how to use labels in combination with fonts.

#### Add Databanks

In order to give our application the ability to recognise all that lovely, lovely RAM in the newer '4620 and '4520 PICs, one or a mixture of the following options is required:

#### Standard Bank Size

- In the source of your application, edit project.lkr
- Change

DATABANK	NAME=miosram_u	START=0x380	END=0×5FF	PROTECTED
----------	----------------	-------------	-----------	-----------

Using the	PIC18F4620	or PIC18F4520
-----------	------------	---------------

2025/08/04 14:53	7/1	10	Us	ing the PIC18F4620 or PIC18F4520
ACCESSBANK	NAME=accesssfr	START=0xF80	END=0×FFF	PROTECTED
То				
DATABANK DATABANK DATABANK DATABANK DATABANK DATABANK DATABANK DATABANK DATABANK DATABANK	NAME=miosram_u NAME=gpr6 NAME=gpr7 NAME=gpr8 NAME=gpr9 NAME=gpr10 NAME=gpr11 NAME=gpr12 NAME=gpr13 NAME=gpr14 NAME=gpr15	START=0x380 START=0x600 START=0x700 START=0x800 START=0x900 START=0xA00 START=0xB00 START=0xC00 START=0xC00 START=0xE00 START=0xF00	END=0×5FF END=0×6FF END=0×7FF END=0×8FF END=0×9FF END=0×AFF END=0×BFF END=0×CFF END=0×CFF END=0×EFF END=0×F7F	PROTECTED
ACCESSBANK	NAME=accesssfr	START=0×F80	END=0×FFF	PROTECTED

#### **Extended Bank Capacity**

The above change will enable SDCC to allocate the variables in your application to any of the specified banks above. The very observant among you may have noticed that these banks are 256 bits each.... So what happens if you want to use a variable which is greater than 256 bits in size, such as a large array, or string of characters? For this, you will need to create a bank of extended size, and you will need to direct your application to use that bank to store your large variable.

In order to create memory banks of extended capacity, it is necessary to section off a greater range than those given above. A good way to go about this is to combine two or more of the default banks. The following are examples of this.

Making a single, 512-bit bank:

DATABANK NAME=miosram_u	START=0x380	END=0x5FF	PROTECTED
// DATABANK NAME=gpr6	START=0x600	END=0×6FF	
<pre>// Remove this bank</pre>			
// DATABANK NAME=gpr7	START=0x700	END=0x7FF	
<pre>// And remove this bank</pre>			
DATABANK NAME=gpr67	START=0×600	END=0x7FF	
<pre>// And create this one out</pre>	of the two		
DATABANK NAME=gpr8	START=0x800	END=0x8FF	
DATABANK NAME=gpr9	START=0×900	END=0x9FF	
DATABANK NAME=gpr10	START=0×A00	END=0×AFF	
DATABANK NAME=gpr11	START=0×B00	END=0×BFF	
DATABANK NAME=gpr12	START=0×C00	END=0xCFF	
DATABANK NAME=gpr13	START=0×D00	END=0xDFF	
DATABANK NAME=gpr14	START=0×E00	END=0xEFF	
DATABANK NAME=gpr15	START=0×F00	END=0xF7F	

ACCESSBANK NAME=accesssfr START=0xF80 END=0xFFF PROTECTED

Note that the START of the bank is the same as the START of the first bank removed, and the END of the bank, is the same as the END of the last bank removed.

This can be extended into larger ranges, and multiple customised ranges, as below:

DATABANK NAME=miosram_u // DATABANK NAME=gpr6 // Remove this bank,		END=0x5FF END=0x6FF	PROTECTED
<pre>// DATABANK NAME=gpr7 // And remove this bank,</pre>	START=0x700	END=0x7FF	
DATABANK NAME=gpr67	START=0×600	END=0x7FF	
// And create this 512-bit	bank out of the two	256-bit banks.	
DATABANK NAME=gpr8	START=0x800	END=0x8FF	
DATABANK NAME=gpr9	START=0×900	END=0x9FF	
DATABANK NAME=gpr10	START=0×A00	END=0×AFF	
// DATABANK NAME=gpr11	START=0×B00	END=0×BFF	
<pre>// Remove this bank,</pre>			
// DATABANK NAME=gpr12	START=0×C00	END=0×CFF	
<pre>// And remove this bank,</pre>			
// DATABANK NAME=gpr13	START=0×D00	END=0×DFF	
<pre>// And remove this bank,</pre>			
// DATABANK NAME=gpr14	START=0×E00	END=0×EFF	
<pre>// And remove this bank!</pre>			
DATABANK NAME=gpr1114		END=0xEFF	
<pre>// And create this 1024-bi</pre>		it of the four 2	256-bit banks.
DATABANK NAME=gpr15	START=0×F00	END=0xF7F	
ACCESSBANK NAME=accesssfr	START=0×F80	END=0×FFF	PROTECTED

Or of course you could make the whole lot into one bank if you wanted to:

DATABANK DATABANK // That's	NAME=miosram_u NAME=gpr615 almost 2.5kilobi	START=0×600	END=0×5FF END=0×F7F	PROTECTED
ACCESSBANK	NAME=accesssfr	START=0xF80	END=0xFFF	PROTECTED

### **Add Sections**

In order to assist in the use of these memory banks, we can give create 'sections' with names, and those names can be referenced in our code later on. I will use the 2nd example above, to demonstrate:

2025/08/04 14:53 9/10 END=0x5FF DATABANK NAME=miosram u START=0x380 PROTECTED DATABANK NAME=gpr67 START=0x600 END=0x7FF // And create this 512-bit bank out of the two 256-bit banks. DATABANK NAME=gpr8 START=0x800 END=0x8FF DATABANK NAME=apr9 START=0x900 END=0x9FF DATABANK NAME=gpr10 START=0xA00 END=0xAFF DATABANK NAME=gpr1114 START=0xB00 END=0xEFF // And create this 1024-bit (1 Kilobit) bank out of the four 256-bit banks. DATABANK NAME=gpr15 START=0xF00 END=0xF7F ACCESSBANK NAME=accesssfr START=0xF80 END=0xFFF PROTECTED SECTION NAME=CONFIG ROM=config // This SECTION entry will already exist in the file. Do NOT alter this line! SECTION NAME=gpr8 RAM=gpr8 // This creates a SECTION called 'gpr8' which references the normal 256-bit bank 'gpr8' SECTION NAME=b512 RAM=gpr67 // This creates a SECTION called 'b512' which references our 512-bit bank NAME=b1024 RAM=gpr1114 SECTION

// This creates a SECTION called 'b1024' which references our 1kb bank

You may create as many or as few sections as you require for your application.

## **Application Code**

Once these sections are created, you can use them within your application, by forcing a variable to be stored within that section. This is done using the 'udata' pragma statement with the following syntax:

#pragma udata section name variable name

For example, referencing the above section:

```
#pragma udata b512 MIDI Table
                                    // This means "store a variable named
'MIDI_Table' in the SECTION named 'b512'
unsigned int MIDI_Table[512];
                                    // Declare the array named 'MIDI_Table',
and now it will be stored in 'b512'
```

• Upload the hex file with MIOS Studio

Still reading? Shouldn't you be writing code right now? ;)
